

WET TILE THICKNESS CONTROL PROCEDURE 051225

1. Definition and Purpose

Thickness measurement constitutes a fundamental parameter in production control. Its main objective is to ensure that each tile complies with the established reference dimensions and weight, thereby guaranteeing a consistent level of product quality.

2. Internal Control Procedure (Quality)

A systematic control will be implemented through hourly measurements during production, applied to all profiles of the tile.

3. Specific Control Objectives

These measurements allow for:

***Verifying extruder adjustment:** Confirming that the extrusion box is correctly configured to achieve the target thickness and weight.

***Validating component alignment:** Checking that the relative position between the Small Slipper and the Big Slipper is correct, in order to prevent future issues in the interlocking and installation of tiles on the roof.

***Monitoring Slipper wear:** Identifying progressive wear on the profile of the Slippers at the extruder outlet. This wear is directly reflected in the upper profile of the tile during production, causing its deformation and a generalized increase in thickness and weight. It serves as a key indicator for preventive maintenance.

***Monitoring Roller wear:** The wear on the Big Roller and Small Roller is identified by measuring the diameters at their predefined reference zones.
